SHORT REFLECTION

1. What functions did you create in your calculator program?
- The functions I created in my calculator program are add(a, b), subtract(a, b), multiply(a, b), and divide(a,b).

2. What parameters did your functions use?
- All my functions used the same parameter, a and b.

3. What arguments were passed when the functions were called?
- When the functions are called inside the if-elif blocks, the arguments passed to them are the first_number and second_number

4. How did your program use the returned value?
- The program saves the returned value into a variable named result. It then checks the data type of the result.

5. Why is it better to divide the calculator program into functions instead of writing everything in one long block of code?
- It is better to divide the calculator program into functions instead of writing everything in one block of code so that your program won't be too long or confusing to understand. Also, if there is anything wrong with your code, it is easier to find the problem and debug.
